HERPETOLOGICAL REVIEW

SOCIETY FOR THE STUDY OF AMPHIBIANS AND REPTILES

www.ssarherps.org

The Society for the Study of Amphibians and Reptiles, the largest international herpetological society, is a not-for-profit organization established to advance research, conservation, and education concerning amphibians and reptiles. Founded in 1958, SSAR is widely recognized today as having the most diverse society-sponsored program of services and publications for herpetologists. Membership is open to anyone with an interest in herpetology—professionals and serious amateurs alike—who wish to join with us to advance the goals of the Society.

All members of the SSAR are entitled to vote by mail ballot for Society officers, which allows overseas members to participate in determining the Society’s activities; also, many international members attend the annual meetings and serve on editorial boards and committees.

All members and institutions receive the Society’s primary technical publication, the Journal of Herpetology, and its bulletin, Herpetological Review; both are published four times per year. Members also receive pre-publication discounts on other Society publications, which are advertised in Herpetological Review.

To join SSAR or to renew your membership, please visit the secure online ZenScientist website via this link: http://www.ssarherps.org/pages/membership.php

Future Annual Meetings
2015 — Lawrence, Kansas 30 July–3 August (SSAR with PARC and KHS)

tymanum, although there was little blood. The lizard was left at the site in case the kestrel returned for it. The air temperature at the time of the observation was ~35°C.

Although we did not observe prey capture, kestrels are generally hunters rather than scavengers (Olsen et al. 1979. Emu 79:133–138), suggesting that the raptor caught and killed the lizard just before we arrived (the lizard was in good condition). It is possible that the reproductive condition of the lizard contributed to its vulnerability to capture, as it was heavily egg-laden. Ring-tailed Dragons are common at the site, and are generally common in rocky areas where they forage for insects during the day, often at very hot temperatures. Kestrels are also relatively common at the site, and lizards are generally an important prey item; in one study lizards made up ~90% of prey items by weight (Aumann 2001. Wildl. Res. 28:379–393). In that study agamids were found in 53% of regurgitated pellets, and C. nuchalis, a congener of C. caudicinctus, was the most common reptilian prey item.

**J. SEAN DOODY**, Department of Ecology & Evolutionary Biology, University of Tennessee, 569 Dabney Hall, Knoxville, Tennessee 37996-1610, USA (e-mail: jsdoody@gmail.com); BRENDAN SCHEMBRI, 2/26 Sergison Circuit, Rapid Creek, Northern Territory 0810, Australia (e-mail: herpo88@hotmail.com).

**DAREVSKIA BRAUNERI** (Brauner’s Rock Lizard). **DIET.** The diet of *Darevskia brauneri* is known to consist mainly of insects, other invertebrates, berries, and overripe fruit (Darevsky 1967. Rock Lizards of the Caucasus: Systematics, Ecology and Phylogeny of the Polymorphic Groups of Caucasian Rock Lizards of the Subgenus Archaeolacerta. Nauka, Leningrad. 214 pp. [in Russian; English translation published by the Indian National Scientific Documentation Centre, New Delhi, 1978]). However, on 28 August 2001 on rocky outcrops of the valley of the Mzymta River in the village of Esto-Sadok, Krasnodar Krai, Russia (43.68093°N 40.27605°E; 550 m elev.) we observed an adult female holding a juvenile specimen of *Lacerta agilis* (Sand Lizard) in its jaws. This is the first recorded case of a lizard of the genus *Darevskia* preying on a vertebrate. An earlier report in the literature recorded the opposite case of *L. agilis* preying upon a lizard of the genus *Darevskia* (*D. pontica*) (Zhukov 1941. K sistematike, rasprostraneniyu i biologii Lacerta praticola Eversmann [Reptilia, Sau- ria] [Systematic, distribution and biology of Lacerta praticola Eversmann (Reptilia, Sauria)]. Proc. Krasnodar State Pedagogical Institute named after the 15th anniversary of the Komsomol. Krasnodar. Vol. 8. pp. 326–335 [in Russian]).

DORONIN, Department of Herpetology, Zoological institute of Russian Academy of Sciences, St. Petersburg 199034, Russia (e-mail: ivdoronin@mail.ru).

**ELGARIA PAUCICARINATA** (San Lucan Alligator Lizard). **FIELD AND PREFERRED BODY TEMPERATURES.** *Elgaria paucicarinata* is a small terrestrial lizard endemic to the mountain and foothill habitats of the Cape Region in Baja California (Grismer 2002. Amphibians and Reptiles of Baja California, Including its Pacific Islands and the Islands in the Sea of Cortés. Univ. California Press, Berkeley and Los Angeles, California. 399 pp.). Little is known about the ecology of this lizard, and even less about the thermal ecology. We present data on *E. paucicarinata* thermal ecology from Sierra de La Laguna Biosphere Reserve on the Cape Region, Baja California Sur, México. We conducted fieldwork at Segundo Valle (23.55251°N, 109.98689°W, WGS84; elev. 1770 m) on 12–14 July and 20–22 September 2011. The site is predominated by pine-oak forest vegetation (e.g., *Pinus lagunae, Quer- cus devia, Arbutus peninsularis*), perennial herbs, leaf litter, and granitic rocks (Arriaga and Ortega [eds.] 1988. La Sierra de la Laguna de Baja California Sur. CIBNR, Mexico. 247 pp.). Data are based on 20 individuals (adults and juveniles) captured by hand between 0900 and 1900 h. Sex was not determined because of the lack of sexually dimorphic characters. We measured body temperature (T_b) and air temperature (T_a) with a quick-reading thermometer (Fluke 52 K/J type) immediately following capture. The substrate temperature (T_s) was measured with a non-contact infrared thermometer (Raytek Raynger ST®) at the exact point where the animal was first sighted and T_a 2 cm above the substrate. We recorded data on snout–vent length (SVL), time of capture, microhabitat type, and light condition (full sunlight, filtered sunlight, and full shade). We brought five adult individuals into a laboratory thermal gradient to measure the preferred body temperatures (T_p). The thermal gradient consisted of a glass terrarium 76 × 30 × 45 cm (long/width/height), with soil and leaf litter, located in a room with a controlled temperature of 20°C. We offered a thermal gradient of 20–37°C by placing two 100-W day-light blue bulbs at different heights in one end of the terrarium. We took body temperatures every hour between 0900 and 1500 h, with the same thermometer used in the field.

Mean SVL was 96.8 mm (SD = 20.6, range: 58–120 mm, N = 12). Mean field T_a was 25.4°C (SD = 3.2, range: 20–31.2°C, N = 20). Mean T_b was 20.8°C (SD = 1.5, range: 17.5–24.1°C) and mean T_s was 24°C (SD = 3.6, range: 19.2–31.8°C). Both T_b and T_s were significantly correlated with body temperature (Spearman Rank Correlation, r_s = 0.80, r_s = 0.84, P = 0.0001, respectively). Most lizards were found on leaf litter with plant cover (N = 13), followed by leaf litter on open areas (N = 5), oak logs, and rocks (N = 1); and in full shade microhabitats (N = 11), followed by full sunlight (N = 6) and filtered sunlight (N = 3). The mean T_b was 25.8°C (SD = 3.4, range = 20.5–30.9°C). Intequarentile of 25% and 75% was 24.6°C and 27.9°C, respectively. *E. paucicarinata* mean body temperature is higher than other *Elgaria* species (*E. coerulea* = 15.8°C, Brattstrom 1965. Am. Midl. Nat. 73[2]:376–422; *E. multicarinata* = 21°C, Beck 2009. In Jones and Lovich [eds.], Lizards of the American Southwest, pp. 484–487. Rio Nuevo Publishers, Tucson, Arizona). Compared with other gerrhonotine lizards, *E. paucicarinata* has a slightly lower T_b than *Barisia imbricata* (26.8°C; Lemos-Espinal et al. 1998. Amphibia-Reptilia 19:95–99). The positive correlation of T_b with T_s and T_a suggests that *E. paucicarinata* is not clearly thigmothermic or heliothermic. Light condition preference data give support to a thigmothermic model where lizards gain heat by moving between microhabitats with different sunlight categories, because lizards were found in open and plant-covered areas. The similarity of T_p and field T_s suggests that *E. paucicarinata* thermoregulates, but an assessment of the thermal environment is needed to determine the patterns of thermoregulation of this species.

We thank Anny Peralta-Garcia for comments on the manuscript, and Abelino Cota and Franco Cota for their help during fieldwork.
